

5.353 weighted_partial_alldiff

	DESCRIPTION	LINKS	GRAPH
Origin	[368, page 71]		
Constraint	weighted_partial_alldiff(VARIABLES, UNDEFINED, VALUES, COST)		
Synonyms	weighted_partial_alldifferent, weighted_partial_alldistinct, wpa.		
Arguments	VARIABLES : collection(var-dvar) UNDEFINED : int VALUES : collection(val-int, weight-int) COST : dvar		
Restrictions	required(VARIABLES, var) VALUES > 0 required(VALUES, [val, weight]) in_attr(VARIABLES, var, VALUES, val) distinct(VALUES, val)		

Purpose All variables of the VARIABLES collection that are not assigned to value UNDEFINED must have pairwise distinct values from the val attribute of the VALUES collection. In addition COST is the sum of the weight attributes associated with the values assigned to the variables of VARIABLES. Within the VALUES collection, value UNDEFINED must be explicitly defined with a weight of 0.

Example

$$\left(\begin{array}{l} \text{var} - 4, \\ \text{var} - 0, \\ \left\langle \begin{array}{l} \text{var} - 1, \\ \text{var} - 2, \end{array} \right\rangle, 0, \\ \text{var} - 0, \\ \text{var} - 0 \\ \text{val} - 0 \quad \text{weight} - 0, \\ \text{val} - 1 \quad \text{weight} - 2, \\ \left\langle \begin{array}{l} \text{val} - 2 \quad \text{weight} - -1, \\ \text{val} - 4 \quad \text{weight} - 7, \\ \text{val} - 5 \quad \text{weight} - -8, \\ \text{val} - 6 \quad \text{weight} - 2 \end{array} \right\rangle, 8 \end{array} \right)$$

The weighted_partial_alldiff constraint holds since:

- No value, except value UNDEFINED = 0, is used more than once.
- COST = 8 is equal to the sum of the weights 2, -1 and 7 of the values 1, 2 and 4 assigned to the variables of VARIABLES = ⟨4, 0, 1, 2, 0, 0⟩.

Symmetries

- Items of VARIABLES are [permutable](#).
- Items of VALUES are [permutable](#).
- All occurrences of two distinct values in VARIABLES.var or VALUES.val that are both different from UNDEFINED can be [swapped](#); all occurrences of a value in VARIABLES.var or VALUES.val that is different from UNDEFINED can be [renamed](#) to any unused value that is also different from UNDEFINED.

Usage

In his PhD thesis [368, pages 71–72], Sven Thiel describes the following three potential scenarios of the `weighted_partial_alldiff` constraint:

- Given a set of tasks (i.e., the items of the VARIABLES collection), assign to each task a resource (i.e., an item of the VALUES collection). Except for the resource associated with value UNDEFINED, every resource can be used at most once. The cost of a resource is independent from the task to which the resource is assigned. The cost of value UNDEFINED is equal to 0. The total cost COST of an [assignment](#) corresponds to the sum of the costs of the resources effectively assigned to the tasks. Finally we impose an upper bound on the total cost.
- Given a set of persons (i.e., the items of the VARIABLES collection), select for each person an offer (i.e., an item of the VALUES collection). Except for the offer associated with value UNDEFINED, every offer should be selected at most once. The profit associated with an offer is independent from the person that selects the offer. The profit of value UNDEFINED is equal to 0. The total benefit COST is equal to the sum of the profits of the offers effectively selected. In addition we impose a lower bound on the total benefit.
- The last scenario deals with an application to an over-constraint problem involving the [alldifferent](#) constraint. Allowing some variables to take an "undefined" value is done by setting all weights of all the values different from UNDEFINED to 1. As a consequence all variables assigned to a value different from UNDEFINED will have to take distinct values. The COST variable allows to control the number of such variables.

Remark

It was shown in [368, page 104] that, finding out whether the `weighted_partial_alldiff` constraint has a solution or not is NP-hard. This was achieved by reduction from [subset sum](#).

Algorithm

A filtering algorithm is given in [368, pages 73–104]. After showing that, deciding whether the `weighted_partial_alldiff` has a solution is NP-complete, [368, pages 105–106] gives the following results of his filtering algorithm with respect to consistency under the 3 scenarios previously described:

- For scenario 1, if there is no restriction of the lower bound of the COST variable, the filtering algorithm achieves [arc-consistency](#) for all variables of the VARIABLES collection (but not for the COST variable itself).
- For scenario 2, if there is no restriction of the upper bound of the COST variable, the filtering algorithm achieves [arc-consistency](#) for all variables of the VARIABLES collection (but not for the COST variable itself).
- Finally, for scenario 3, the filtering algorithm achieves [arc-consistency](#) for all variables of the VARIABLES collection as well as for the COST variable.

Graph model

Parts (A) and (B) of Figure 5.637 respectively show the initial and final graph associated with the **Example** slot. Since we also use the **SUM** graph property we show the vertices of the final graph from which we compute the total cost in a box.
